TTTech Computertechnik AG

2006 MAPLD International Conference,  
Washington, DC

David A. Gwallney  
NASA

**The Integrated Safety-Critical Advanced Avionics Communication & Control (ISACC) System is the product of the Propulsion High-Impact Avionics Technologies (PHIAT) project at NASA Marshall Space Flight Center (MSFC) during FY03 to the end of FY05**

Originally funded under Next Generation Launch Technologies (NGLT) for four years beginning in mid FY03

- Tasked to develop avionics technologies for control of next generation reusable rocket engines
- Funded under the Exploration Systems Mission Directorate (ESMD) through end of FY05
- Broadened scope to include vehicle systems control for human and robotic missions

**The goal is an avionics architecture suitable for control and monitoring of safety critical systems of manned spacecraft**

- Scalable to allow its use in robotic vehicles or launch pad and propulsion test stand monitoring and control systems.

## Technical Background

# TIItech

**Four primary areas of focus for the ISAAAC distributed real-time control system to provide a reliable system for human spaceflight, while also providing scalability and addressing cost sensitivity and sustaining engineering.**

- Modular components
  - High reusability
  - Flexibility to accommodate upgrades
  - Limit number of unique designs
  - Scalable
- Hard real-time, safety critical communications between modules and systems of modules
  - Fault detection, containment and tolerance
  - High availability, High reliability
  - Guaranteed quality of service – low jitter/latency
- Distributed intelligence
  - Complex functionality using processing elements with moderate capability (i.e. Current Rad Hard processors/FPGAs )
  - Fault Tolerance / Fault Detection, Isolation and Recovery (FDIR)
- Plug-and-Play / Hot Swap at all levels (Modules, Transducers, Controlled Components)
  - Improved maintainability
  - Increased flexibility
  - Reduce cost of software changes / unique software configurations

## Federated vs. IMA Systems

TTTech

### Federated

- every LRU/ECU has one function only
- Power supply & rugged chassis for every LRU
- Excessive weight, higher system integration hard to accomplish

### Integrated Modular Avionics (IMA)

- Common power supply & rugged chassis for a set of modules
- many upgradeable SW functions on one module (i.e. processing unit)
- Reduced weight, straightforward update and system integration
- Partitioning and MMU important!

*Note: MMU=Memory Management Unit*

## Distributed IMA vs. IMA Systems

**TITech**

### IMA philosophy

- Run many partitioned functions on one embedded computer
- Use shared resources (processing time, I/O, power supply, ...)

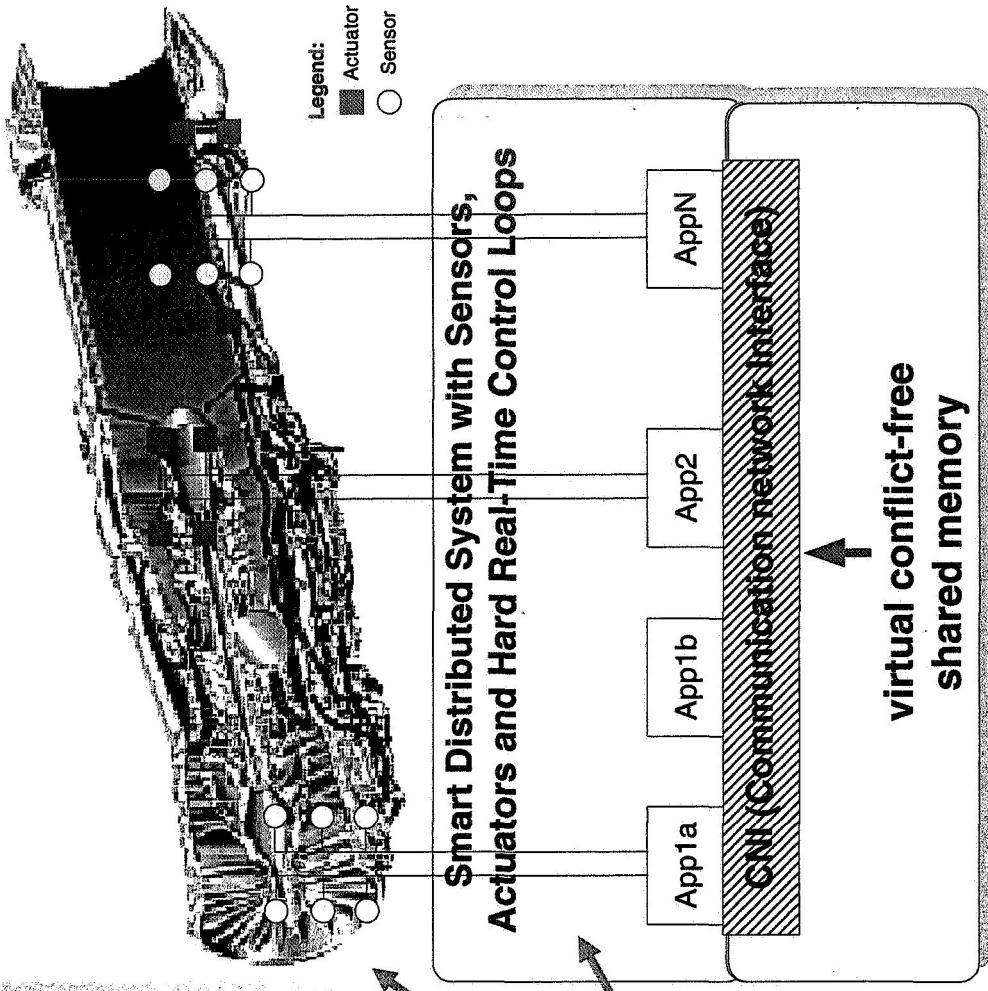

### Distributed IMA philosophy

- Run many partitioned functions on one distributed fault-tolerant embedded computer
- Share common communication medium

## TTP: A Distributed IMA Platform Technology

**“The network is a deterministic fault-tolerant hard real-time embedded computer”**

- System architecture with system redundancy and voting
- System health monitoring and high data integrity
- Strictly deterministic communication (max. 25MBit/s)
- System synchronization (jitter in  $\mu$ s range)

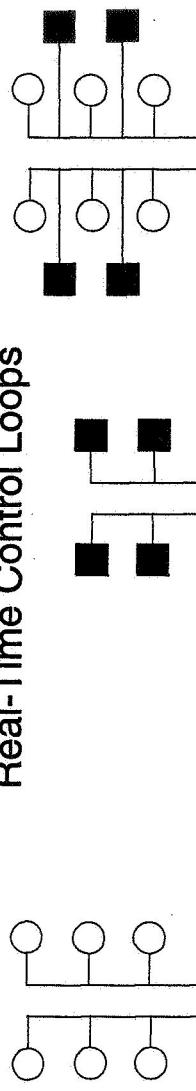

**Application designer focused on:**

- application-specific issues
- fast real-time control loops

# TTTech: Built-in Distributed Services

TTTech

CNI

TTP  
Controller

TTP Communication Network  
with Built-In Health Monitoring and Redundancy Services

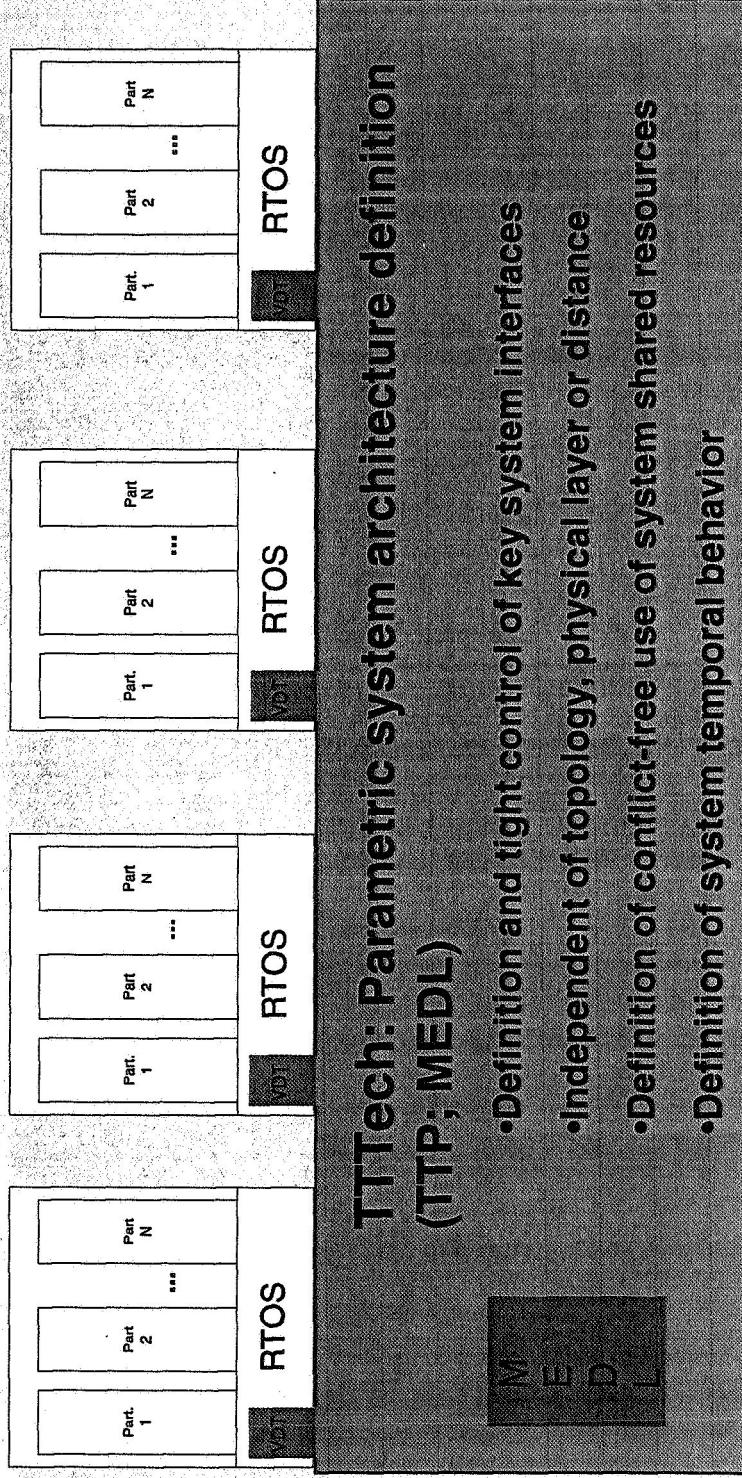

On-chip TTP protocol guarantees autonomous operation of communication system, independent of application host/software:

# TTP: Parametric System Design

## Parametric design of LRU software behavior (RTOS, def. table)

- Standard software application interfaces
- Definition of conflict-free use of shared resources
- Definition of LRUs temporal behavior

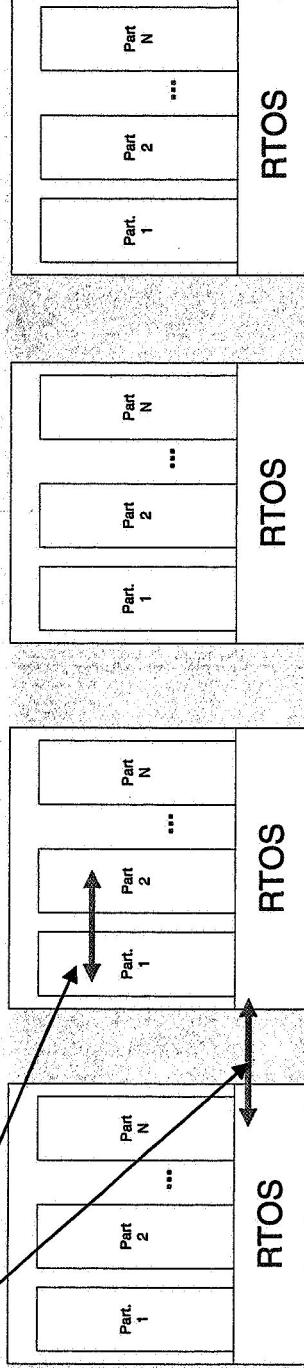

## TTP: System (not only LRU SW!) Partitioning

### Software partitioning using MMU and scheduled resource use

- No fault propagation to other software partitions
- Conflict-free use of shared resources among partitions (I/O, memory, ...)
- MMU may be a weak point -> solution by using one partition per LRU!

### Fault Isolation

### TTTech: System Partitioning using TDMA and other TTP mechanisms

- No control error propagation to other LRUs after (single) HW or SW fault
- Prevention of timing violations of controller by bus guardian
- Conflict-free use of communication resource among LRUs
- Communication system operates autonomously, based on predefined schedule, distributed network management and fault-tolerant time base

## Benefits (I)

### Reduced (re)design costs

- Simplified design of complex integrated systems
- Reduced upgrade/extension/reconfiguration costs

### Reduced integration and system testing costs

- integration provided per default
- no jitters, hazards, coupled temporal/logical effects and fault propagation
- **concurrent engineering and separate testing possible!**

### Simplified design for system autonomy

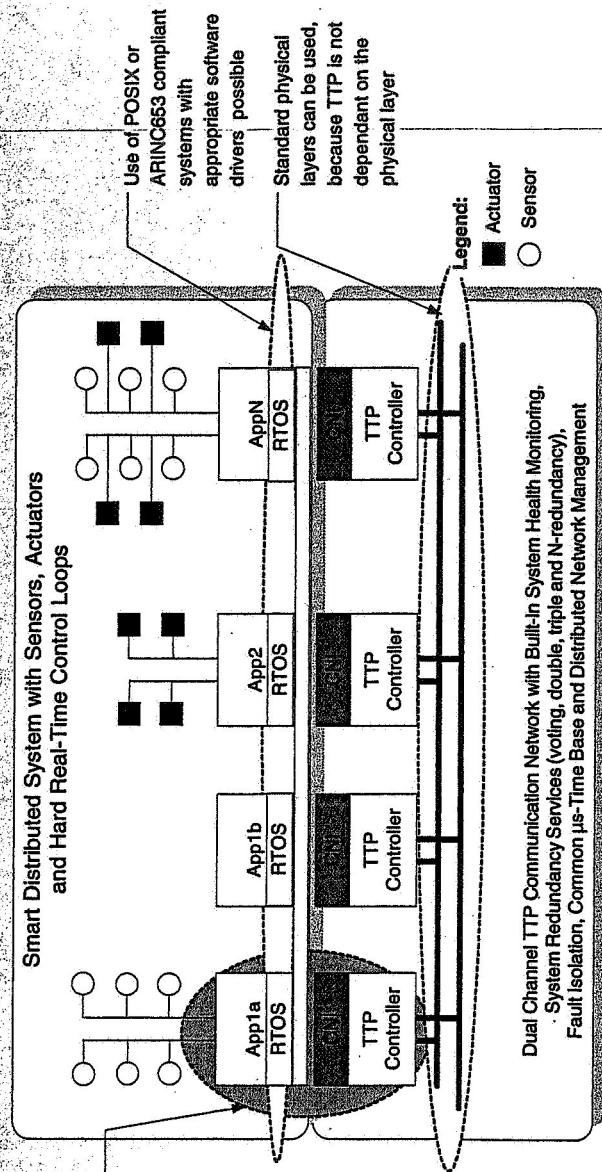

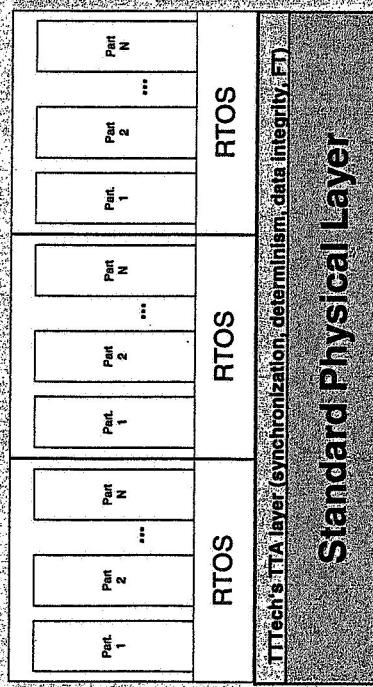

- Improved stability as a result of strict control of key interfaces and system partitioning
- Simplified design of redundant systems and graceful degradation due to the built-in services

## Benefits ( )

# TTech

Reduced obsolescence management costs

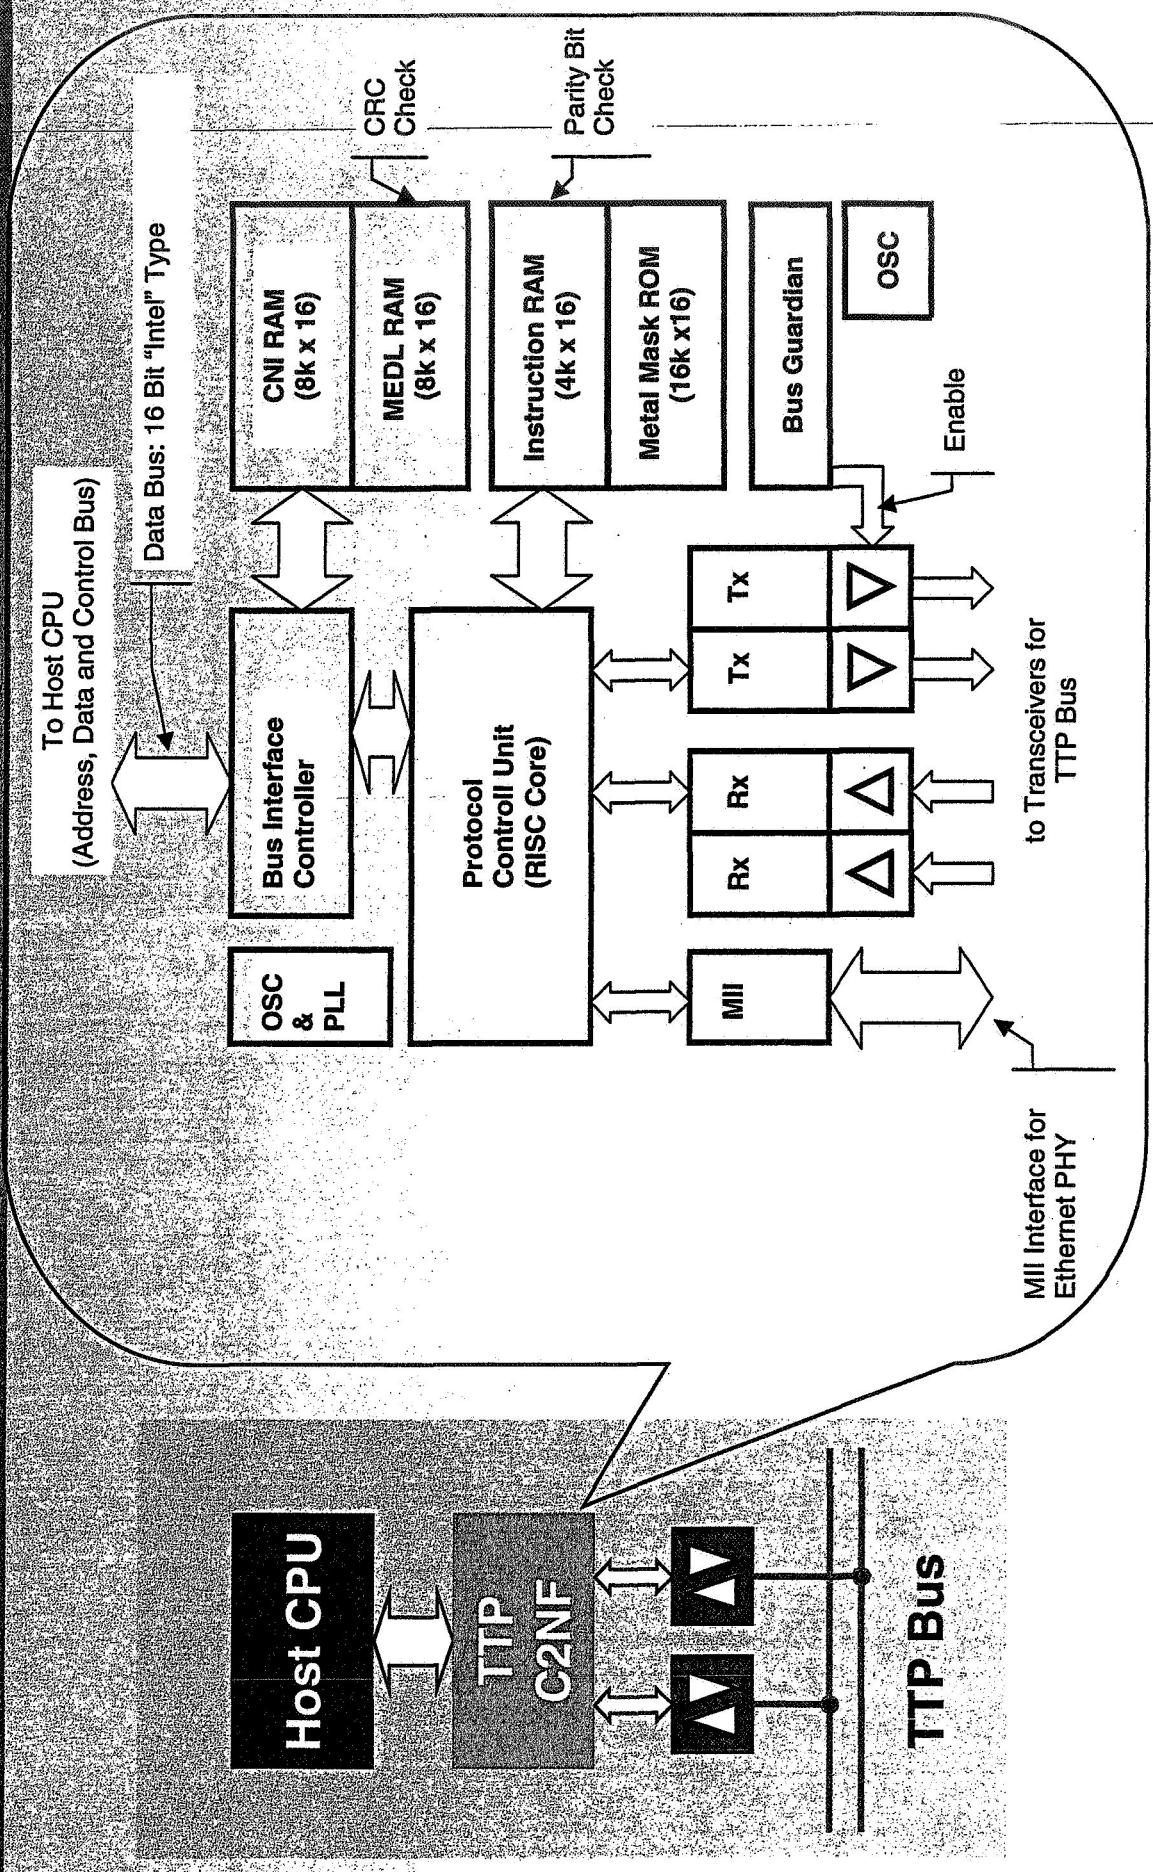

- Application software can be made independent of:
  - OS version (e.g. 2.0 vs. 4.0)
  - Host hardware
    - system redundancy scheme
    - Physical layer / communication speed
  - TTP as a thin layer between standard components

- Dual Channel TTP Communication Network with Built-In System Health Monitoring,
- System Redundancy Services (voting, double, triple and N-redundancy),
- Fault Isolation, Common Bus-Time Bases and Distributed Network Management

# C2NF – TTTech's Chip IP for TTP Control

TTTech

## C2NF Model Features

**TTTech**

## C2NF = TTP Controller with Processor Unit Core

- Fulfils TTP Protocol Specification
- Proprietary processor unit (RISC)
- TTP data transmission using MFM and Manchester coding
- MII interface for high speed Physical Layer
- 16 bit non-multiplexed host CPU interface
- 16k x 16 instruction ROM
- 16k x 16 MEDL and CNI SRAM
- 4k x 16 instruction SRAM

*Notes:*

*MEDL = Message Descriptor List ; configuration register*

*CNI = Controller Network Interface ; dual ported RAM*

### Project: Space application

- Available standard controllers (e.g. AS8202NF by austriamicrosystems) are not qualified for space use
- C2NF implementation must be radiation tolerant
- Selected FPGAs family RTAX 2000 (Actel)
- Major issues: limited RAM size, no PLLs

### Study

- Evaluate required restrictions to original C2NF model
- Preliminary assumption: reduction of message buffer is necessary
- Evaluate impact to development tools and TTP network performance
- Target prototype with AX2000 devices (considering RT impacts)

## C2NF – Rad Hard Implementation

TTTech

*TBD. – work in progress*

*Here FPGA implementation study results will be introduced if available at the time of the conference.*

## Future Outlook: Technology Development

# TTTech

### Today:

- Specification stable since 2002
- Chips available since 1998

### Tomorrow:

- More communication speed
- Advanced distributed services
- Improved support for IVHM

*Note: IVHM = Integrated Vehicle Health Management*

## Future Outlook: Industry Applications

# TTTech

### Today:

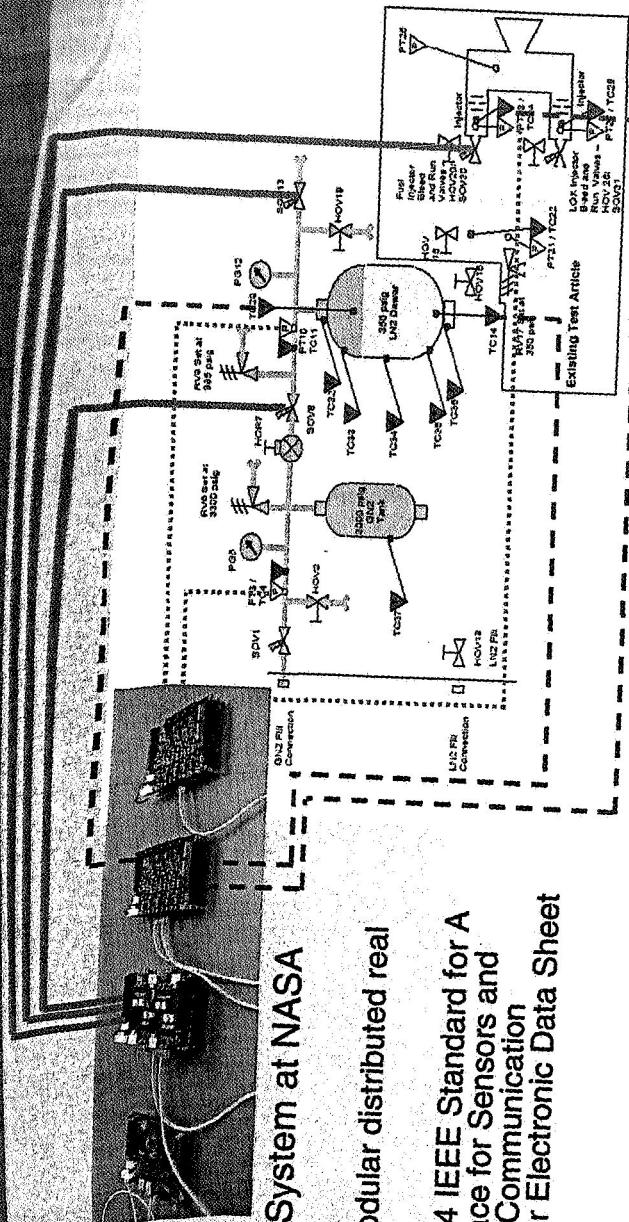

- Control systems for Boeing 787
- Control systems for Airbus A380
- Control systems for military aircraft (F-16, M-346)
- Control systems for DARPA Grand Challenge (Red Team)

### Tomorrow:

- Design wins of new „more electric“ aircraft (commercial/military)
- Design wins of new unmanned systems (UAV/UUV/UGVs)
- Design wins of new space systems

# TTTech

## Future Outlook: Space Application

Today:

- Aerospace Development System at NASA MSFC
  - TTP is backbone of a modular distributed real time control system
  - Incorporates IEEE 1453.4 IEEE Standard for A Smart Transducer Interface for Sensors and Actuators—Mixed-Mode Communication Protocols and Transducer Electronic Data Sheet (TEDS) Formats
  - Plug-n-play sensors
  - Stackable function boards to tailor functionality at distributed modules
  - Tested as controller for simulated pressure fed rocket engine – prototype for methane/IOX engine

## Future:

- Continued refinement of development system for space applications through partnerships with Johnson Space Center and Kennedy Space Center
- Candidate for use in control of critical subsystems in future launch vehicles and manned spacecraft
- Candidate for Test Stand Operation – i.e. Methane/LOX engine hotfire testing at MSFC
- Candidate for Lunar missions – robotic and control of subsystems for lunar base infrastructure
